## Rate of Return Analysis Single Alternatives

# Multiple Rate of Return Values

- We have so far come across net cash flows that change **once** during the investment period
- That is, we started with a negative value at the very beginning (initial payment) and the cash flows became positives (incomes)
- This situation is called conventional (simple) cash flow series

# Multiple Rate of Return Values

- In many situations, the net cash flows **switch** between **positive** and **negative** values from year to another so that we have more than one sign change
- Such series is called non-conventional (non-simple)

# Multiple Rate of Return Values

| Type of Series  | Sign on Net Cash Flow |   |   |   |   |   |   | Number of Sign Changes |
|-----------------|-----------------------|---|---|---|---|---|---|------------------------|
|                 | 0                     | 1 | 2 | 3 | 4 | 5 | 6 |                        |
| Conventional    | -                     | + | + | + | + | + | + | 1                      |
| Conventional    | -                     | - | - | + | + | + | + | 1                      |
| Conventional    | +                     | + | + | + | + | - | - | 1                      |
| Nonconventional | -                     | + | + | + | - | - | - | 2                      |
| Nonconventional | +                     | + | - | - | - | + | + | 2                      |
| Nonconventional | -                     | + | - | - | + | + | + | 3                      |

Examples of *conventional* and *non-conventional* net cash flows for a 6-year project

# Multiple Rate of Return Values

- When there is *more than one* sign change in the net cash flows, it is possible that there will be **multiple**  $i^*$  values in the -100% to plus infinity range
- A **test** should be performed on the non-conventional series to determine if there is one unique or multiple  $i^*$  values
- Rule of signs: total number of real-number roots is always **less than or equal** to the number of sign changes in the series

# Multiple Rate of Return Values

## Example [1]

Calculate the  $i^*$  values for the following cash flows:

| Year | 0      | 1    | 2      | 3      |
|------|--------|------|--------|--------|
| \$   | +2,000 | -500 | -8,100 | +6,800 |

# Multiple Rate of Return Values

## Example [1]

PW =

$$2,000 - 500(P/F,i,1) - 8,100(P/F,i,2) + 6,800(P/F,i,3)=0$$

| i   | PW        |
|-----|-----------|
| 0%  | \$200.00  |
| 5%  | \$50.97   |
| 10% | -\$39.82  |
| 15% | -\$88.44  |
| 20% | -\$106.48 |
| 25% | -\$102.40 |
| 30% | -\$82.39  |
| 35% | -\$51.01  |
| 40% | -\$11.66  |
| 45% | \$33.13   |
| 50% | \$81.48   |

- If we examine the sign change we find out the following sequence:

+ - - +  
0 to 1 to 1 to 2

- So, we have at most two potential rates of return values

# Multiple Rate of Return Values

## Example [1]
